Limitations ofGenerative AI

1)Large language models (LLMs) are prone to "hallucinations" - generating fictitious information, presented as factual or accurate. This can include citations, publications, biographical information, and other information commonly used in research and academic papers.

2)In addition to fictitious information, answers generated by LLMs can be wrong, often times presented as correct or authoritative.

3)Due to their fundamental structure, as well as regularly released newer versions, content from many generative AI models can be difficult to reproduce consistently. This is particularly problematic in research and academia where reproducibility is a cornerstone of establishing credibility.

4)Generative AI models are not databases of knowledge but rather an attempt to synthesize and reproduce the information they have been trained on. This makes it incredibly difficult to validate and properly attribute the basis of their content,

5)Many common generative AI tools are not connected to the internet and cannot update or verify the content they generate.

6)The nature of generative AI models, particularly when given simple prompts, can be very reductive, resulting in content that is over-simplified, low quality, or very generic.

7)Many generative AI models (including ChatGPT) are trained on data with cutoff dates, resulting in outdated information or the inability to provide answers about current information and events. In some cases, the data cutoff date is not made explicitly clear to the user.
